Q: How to unset shortcut key in emacs I recently installed Emacs using homebrew. The reason I decided to install Emacs was for its language support, specifically this. However, I do not like this shortcut for toggling it off, and I'd like to figure out a way to turn it off. A: When you press you'll see a list of all available shortcuts. Once you press , you'll see a list of currently-defined shortcuts, including the one you're complaining about. Press to go to the shortcut definition, and the shortcut you want to disable (a custom command, perhaps). Press again to go back to the list, and press to disable that command. Then the shortcut you wanted to use again (or M-n to toggle back and forth). Note that once you disable a command, you will have to re-bind it to a key, if you wish to continue using it. Most emacs packages will bind a "good" key to an "evil" key, though, so that you can still use those keybindings even while you're on the "evil" one. Q: How to limit length of a text box to an exact number of characters? I have a simple text box that just puts some text into it. I want to limit the length of that text box to 1000 characters. How to do that? Can I do that? A: `TextBox.TextProperty StringBuilder stringBuilder.Length public static class StringBuilderExtension { public static void Append(this StringBuilder stringBuilder, string value) { if (string.IsNullOrEmpty(value)) return; int length = value.Length; if (stringBuilder.Length + length > MaximumLength)`

What's New in the Photoshop CS5?

Crystallographic evidence that a single monomer of the nontubular multiglycan ectodomain of human erythropoietin does not form a hexameric complex. Erythropoietin (EPO) is a glycoprotein hormone used to treat patients with anemia. It is secreted by the kidneys and is composed of an N-terminal peptide, three disulfide-bridged dimers of two identical polypeptides, and a C-terminal carbohydrate moiety. It has been proposed that the polypeptide chains form an extended beta-trefoil fold structure, which is organized in a six-chain hexagonal array in the native EPO molecule. To understand the nature of interchain interactions, the crystal structure of EPO has been determined using X-ray analysis and is presented here at 2.2 Å resolution. Analysis of EPO data by the MAD technique indicates that the crystallographic dimers are composed of a single polypeptide chain and the crystallographic asymmetric unit, a dimer, contains two dimers related by a twofold rotation axis. The twofold-related dimers of the crystallographic asymmetric unit form a "two-motif" symmetric arrangement, where the beta-trefoil fold of the amino terminus is placed on top of the surface of a calix[6]arene cone and the two identical amino acid sequences are stabilized by three disulfide bridges between loops at the interior of the cone. The five-stranded loop structure and the tertiary structure of these two loops of each dimer are well conserved. Comparison of the crystal structure of EPO to the previously determined structure of a synthetic fragment of the EPO glycosylated nontubular multiglycan ectodomain (X-ray diffraction data collected to 2.3 Å resolution) indicates that the oligosaccharides are incorporated into this multiglycan model as predicted from oligosaccharide composition analysis. Analysis of the complete EPO molecule, however, indicates that the glycan chains are not incorporated into an extended beta-trefoil array. The structure of the EPO monomer suggests that one or two of the two amino acid sequences are detached and can be exchanged with the N-terminal peptide if the EPO molecule is cleaved by enteropeptidase into smaller peptide fragments. That's the big-picture assessment
